

ABSTRACT OF THE INVENTION

A recreational lounge chair which can be used for upright sitting and also for lying prone on one's back or stomach has a seat section and a back section which is pivotally attached. This allows the chair to be converted between an upright chair and a lounge chair for reclining. A footrest section is attached to the seat section and can be pivotable down for upright seating or up for elevating the feet or for reclining in a prone position. The back section includes a through opening configured for the placement of the face of a user lying prone on his or her stomach, when the chair is so configured. The opening is bordered by cushioned pads, for the user's comfort. In this configuration, the user, lying face down and literally looking through the chair, can read a book, as there are cutout openings in the back section of the chair which allows the user to extend his or her arms under the chair, to hold the book. When the user wishes to lie on his or her stomach or sit-up in an upright position, a flap on the undersurface of the back section of the chair is extended and the pads are pivoted over to close the through opening.
